Nonlinear optimization

Problem

 $\min_{x\in C} f(x)$

where $f : \mathbb{R}^n \to \mathbb{R}$ and $C \subseteq \mathbb{R}^n$. (Often both convex, but non-convex becoming more common.)

Applications:

- Economics/finance:
 - Portfolio and risk optimization.
 - Planning/production.
- Engineering:
 - Control.
 - Circuit/structural design.
 - Signal/image processing.
- Statistics and machine learning:
 - Data fitting: classification, regression, matrix completion.
 - Design of experiments.

Numerical methods for nonlinear optimization

► The Early Era: pre-1980s

- First-order methods: gradient descent, Frank-Wolfe, perceptron.
- ► The Medium Scale Era: 1980s-2000s
 - Interior-point & other second order methods
 - Conic programming (second-order cone, semidefinite)
 - Strong theory & industry ready software packages with great accuracy
 - Elaborate algorithms (involving matrix inversion) for generic problems
- ► The Large Scale Era: 2000s-now
 - Lots of data \implies large-scale problems
 - ▶ Goal: modest accuracy & cheap O(n) iterations
 - Resurgence of first-order methods
 - Simple algorithms (matrix inversion-free).

Disclaimer: this does not include progress on **discrete optimization** methods.

◆□ > ◆□ > ◆ □ > ◆ □ > ─ □ = □

Gradient descent and extensions

Consider the problem

$$f^* := \min_{x \in \mathbb{R}^n} f(x).$$

Gradient descent: *f* differentiable

$$x_{k+1} = x_k - t_k \nabla f(x_k).$$

Proximal gradient: f = g + h, g differentiable

$$x_{k+1} = \operatorname*{arg\,min}_{x \in \mathbb{R}^n} \left\{ g(x_k) + \langle \nabla g(x_k), x - x_k \rangle + \frac{t_k^2}{2} \|x - x_k\|_2^2 + h(x) \right\}.$$

Stochastic gradient descent: $f(x) = \mathbb{E}[g(x; \xi)], \xi \sim \mathbb{P}$

$$x_{k+1} = x_k - t_k \nabla_x g(x_k, \xi_k), \quad \xi_k \sim \mathbb{P}.$$

◆□ > ◆□ > ◆三 > ◆三 > ・三 ・ のへで、

Coordinate descent in \mathbb{R}^n

Several key problems have *n* being **very** large. In which case, we run **coordinate descent** (CD) [Beck and Tetruashvili, 2013, Nesterov, 2012]:

• Given x_k , do the following: (cyclic CD)

Set
$$y_{k,0} = x_k$$

for $j \in \{1, \dots, n\}$
 $y_{k,j} = y_{k,j-1} - t_{k,j}e_j \underbrace{e_j^\top \nabla f(y_{k,j-1})}_{=\partial_j f(y_{k,j-1})}$

Set
$$x_{k+1} = y_{k,n}$$
.

(We can also randomly pick the index $j \implies$ randomized CD).

◆□ > ◆□ > ◆ 三 > ◆ 三 > ● の < ⊙

Optimization on manifolds

Manifold domains

$\min_{x \in M} f(x), \text{ where } M \text{ is a manifold.}$

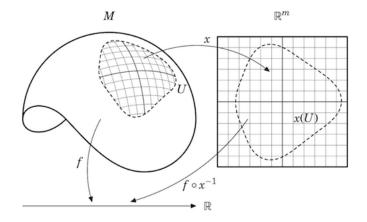

(Informally) M is "locally flat" but (possibly) globally curved set of dimension n on which we can do calculus.

Think about Earth: looks flat from local perspective, but globally curved.

Smooth *n*-Manifold (Formal): topological space *M* that's

- Locally Euclidean and Smooth: Every point x ∈ M has neighborhood U homeomorphic to open set in ℝⁿ.
 - This means locally flat
- Smooth Compatibility: Local Euclidean homeomorphisms are smoothly compatible.
 - Technical, but allows us to do calculus.

Local flatness of manifolds

◆□ ▶ ◆□ ▶ ◆ 三 ▶ ◆ 三 ● ○ ○ ○ ○

Question

What is the benefit of modelling the domain as a manifold?

Answer:

- 1. Some domains have **structural symmetry and/or invariance**, and manifolds are primed to capture various geometric aspects of the domain.
- 2. Some problems are non-convex, but modelling the domain as a manifold *M* and endowing *M* with an appropriate **Riemannian metric** makes them **geodesically convex** (defined later).

3

Manifolds arise in several important applications.

▶ Principal component analysis. Suppose we have points u₁,..., u_K ∈ ℝⁿ with zero mean. Find a *p*-dimensional subspace of ℝⁿ to project the points onto which preserves the variance (as much as possible):

$$\max_{X\in M}\frac{1}{K}\sum_{k\in [K]}\|XX^{\top}u_k\|_2^2, \quad M:=\mathsf{St}(p,n)=\left\{X\in \mathbb{R}^{n\times p}: X^{\top}X=I_p\right\}.$$

Advantages: manifold optimization algorithms implicitly handle the $X^{\top}X = I_p$ constraints by exploiting the structure of the **Stiefel** manifold domain.

Manifolds arise in several important applications.

► Low rank matrix approximation for recommender systems. We have *n* customers and *k* products. Matrix U ∈ ℝ^{n×k} captures ratings, but we only see a few. How can predict unobserved ratings?

$$\min_{X \in M} \sum_{(i,j) \in \Omega \subset [n] \times [k]} (U_{ij} - X_{ij})^2, \quad M := \begin{cases} X \in \mathbb{R}^{n \times k} : C \in \mathbb{R}^{m \times n} \\ P \in \mathbb{R}^{m \times k} \end{cases}$$

The hypothesis is that each customer *i* has an attribute vector $c_i \in \mathbb{R}^m$, each product *j* has an attribute vector $p_j \in \mathbb{R}^m$, then the rating is

$$u_{ij}=c_i^{\top}p_j.$$

(세례) 세금 에서 몸에 드림

Manifolds arise in several important applications:

Gaussian Fisher-Rao distance. The family of non-degenerate zero-mean Gaussians N(0, Σ) can be parametrized by positive definite matrices Σ ∈ Sⁿ₊₊. The Fisher-Rao distance is

$$d(\Sigma_0, \Sigma_1) = rac{1}{\sqrt{2}} \left\| \log \left(\Sigma_1^{-1/2} \Sigma_0 \Sigma_1^{-1/2}
ight) \right\|_F.$$

This has been used in statistical estimation and information geometry.

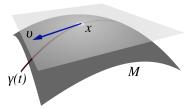

The Fisher-Rao distance is **non-convex** in the Euclidean geometry, but becomes **geodesically convex** when \mathbb{S}_{++}^n is endowed with its **intrinsic metric**.

< ロ > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

First-order methods on manifolds

Concept	General manifold M	$M = \mathbb{R}^n$
directions from $x \in M$	tangent space $T_{x}M\cong\mathbb{R}^{n}$	$T_{x}M\equiv\mathbb{R}^{n}$
gradients of f	$\nabla f(x) \in T_x M$	$ abla f(x) \in \mathbb{R}^n$
Riemannian metric	$\langle \cdot, \cdot angle_{ extsf{x}}$ for each $T_{ extsf{x}}M$	usual inner product
comparing $T_x M$ vs $T_y M$	$\Gamma_x^y: T_x M \to T_y M$	$\Gamma_x^y = I_n$
Movement in a direction	$v\in \mathit{T_x} \mathit{M}\mapsto Exp_{\scriptscriptstyle X}(v)\in \mathit{M}$	$\operatorname{Exp}_{x}(v) = x + v$
distance x, $y = Exp_x(v)$	$d(x,y) = \ v\ _x = \sqrt{\langle v,v\rangle_x}$	$d(x,y) = \ v\ _2$

A function $f : M \to \mathbb{R}$ is geodesically convex if $t \mapsto f(\operatorname{Exp}_x(tv))$ is convex in \mathbb{R} for any $x \in M$, $v \in T_xM$.

Example: positive definite matrices

Consider $M = \mathbb{S}_{++}^n$ [Sra and Hosseini, 2015].

- Tangent space: For $X \in M$, $T_X M = \mathbb{S}^n$.
- Riemannian metric: Given $X \in T_X M$ and $V_1, V_2 \in T_X M$, define

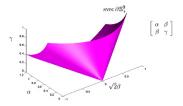

$$\langle V_1, V_2 \rangle_X = \mathsf{Tr}(V_1 X^{-1} V_2 X^{-1}).$$

▶ Parallel transport: Given $X, Y \in M$ and $V \in T_X M$,

$$\Gamma_X^Y(V) = (YX^{-1})^{1/2} V (X^{-1}Y)^{1/2} \in T_Y M.$$

Exponential map: Given $X \in M$, $V \in T_X M$,

$$\operatorname{Exp}_X(V) = X^{1/2} \operatorname{Expm}(X^{-1/2}VX^{-1/2})X^{1/2}.$$

Riemannian Gradient Descent

Consider unconstrained optimization on smooth n-manifold

 $\min_{x\in M}f(x)$

with $f: M \to \mathbb{R}$ differentiable.

Riemannian Gradient Descent:

$$\begin{aligned} x_{k+1} &= \operatorname{Exp}_{x_k}(-t_k \nabla f(x_k)) \\ (x_{k+1} &= x_k - t_k \nabla f(x_k) \quad \text{Euclidean}) \end{aligned}$$

Convergence Rates [Zhang and Sra, 2016]: Under suitable conditions on M and adaption of L-Lipschitz ∇f , if $t_k = \frac{1}{L}$ then

$$\blacktriangleright \min_{i=0,\ldots,k} \|\nabla f(x_i)\|_{x_i} = O\left(\frac{1}{\sqrt{k}}\right) \dots$$

• but if f geodesically convex $\Rightarrow f(x_k) - f^* = O\left(\frac{1}{k}\right)$

◆□▶ ◆□▶ ◆三▶ ◆三▶ ・三 ・ のへで

Subspace descent

Consider the extension of CD to subspace descent:

- ▶ Pick subspaces $\{S_j\}_{j \in [m]}$ such that Span $\left(\bigcup_{j \in [m]} S_j\right) = \mathbb{R}^n$.
- Given x_k , do the following:

Set
$$y_{k,0} = x_k$$

for $j \in \{1, \dots, m\}$
 $y_{k,j} = y_{k,j-1} - t_j P_{S_j} \nabla f(y_{k,j-1})$
Set $x_{k+1} = y_{k,m}$

(Randomized version established by Frongillo and Reid [2015].)

< □ ▶ < □ ▶ < ≧ ▶ < ≧ ▶ Ξ • ⑦ < ♡ 16/31

Tangent subspace descent

Generalization: subspaces of $\mathbb{R}^n \implies$ subspaces of $T_x M$. We call this tangent subspace descent **(TSD)**.

Set
$$y_{k,0} = x_k$$

for $j \in \{1, ..., m\}$
Pick a subspace $S_{k,j} \subset T_{y_{k,j-1}}M$
 $y_{k,j} = \operatorname{Exp}_{y_{k,j-1}}(-t_j P_{S_{k,j}} \nabla f(y_{k,j-1}))$
Set $x_{k+1} = y_{k,m}$

- ▶ In \mathbb{R}^n , the subspaces remain the same.
- On a general $M, S_{k,1}, \ldots, S_{k,m}$ belong to different vector spaces $T_{y_{k,0}}M, \ldots, T_{y_{k,m-1}}M$.
- How should we pick the subspaces?

The problem of subspace selection

If we choose $S_{k,1},\ldots,S_{k,m}$ poorly, then we may not converge.

Theorem

There exists a subspace selection rule and constant $\epsilon > 0$ such that $f(x_k) > \epsilon$ for all k.

Proof idea.

Take $M = \mathbb{R}^n$, $f(x) = \frac{1}{2} ||x||_2^2$, $\operatorname{Exp}_x(v) = x + v$. Choose $\epsilon = ||x_0||_2/4$. For $k \ge 1$, choose

$$S_{k,j} = \text{Span}(\{v_{k,j}\}), \quad ||v_{k,j}||_2 = 1, \ \langle v_{k,j}, y_{k,j-1} \rangle = \sqrt{(f(x_{k-1}) - \epsilon)/m},$$

and
$$y_{k,j} = y_{k,j-1} - \langle v_{k,j}, y_{k,j-1} \rangle v_{k,j}$$
.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 善臣 - のへで

Subspace selection criterion

Lemma (Sufficient decrease leads to convergence)

Suppose there exists $\eta, \eta' > 0$ such that the outer iterates $\{x_k\}$ satisfy

$$f(x_k) - f(x_{k+1}) \ge \eta \| \nabla f(x_k) \|_{x_k}^2$$
 or $f(x_k) - f(x_{k+1}) \ge \eta'$.

Then under suitable regularity conditions on M and f

Lemma (Sufficient decrease)

For appropriately chosen step sizes, there exists C > 0 such that we have

$$f(x_k) - f(x_{k+1}) \ge C \sum_{j \in [m]} \|P_{S_{k,j}} \nabla f(y_{k,j-1})\|_{y_{k,j-1}}^2$$

Key assumption

Assumption (When inner iterates are close, the subspaces are close to orthogonal)

There exists r > 0, $\gamma \in [0, 1]$ such that for any outer iterate $k \ge 1$ the subspaces $\{S_{k,j}\}_{j \in [m]}$ are chosen to generate the inner iterates $y_{k,j}$, $j \in [m]$ so that

there exists an orthogonal decomposition $\{D_{k,j}\}_{j\in[m]}$ of $T_{x_k}M$ such that

$$\max_{j\in[m]} d(x_k, y_{k,j}) < r \implies \left\| \Gamma_{y_{k,j-1}}^{x_k} P_{\mathcal{S}_{k,j}} - P_{D_{k,j}} \right\|_{x_k} \leq \gamma.$$

(We use the induced operator norm from $\langle \cdot, \cdot \rangle_{x_k}$.)

(本間) (本臣) (本臣) (臣)

When does the assumption hold?

- When M = ℝⁿ and the subspace decomposition {S_j}_{j∈[m]} is fixed throughout.
- ▶ When *M* is a product manifolds $M = M^1 \times \cdots \times M^m$. Then for $x = (x^1, \ldots, x^m) \in M$, $T_x M \cong T_{x^1} M^1 \oplus \cdots \oplus T_{x^m} M^m$. Take the subspaces as

$$S_{k,j}=T_{y_{k,j-1}^j}M.$$

For general *M*, fix an orthogonal decomposition {*D_j*^k}_{j∈[m]} of *T_{xk}M*, and at step *j* of iteration *k*, we parallel transport it to *T_{yk,i-1}M*:

$$S_{k,j}=\Gamma_{x_k}^{y_{k,j-1}}D_j^k.$$

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

Convergence result

Lemma

Suppose the assumption holds. Then there exists $\eta, \eta' > 0$ such that

$$\sum_{j\in[m]} d(y_{k,j-1},y_{k,j}) \leq r \implies f(x^k) - f(x^{k+1}) \geq \eta \|
abla f(x^k) \|_{x^k}^2$$
 $\sum_{j\in[m]} d(y_{k,j-1},y_{k,j}) > r \implies f(x^k) - f(x^{k+1}) \geq \eta'.$

Theorem

Suppose the assumption holds, then under suitable regularity conditions on ${\cal M}$ and ${\rm f}$

• if f geodesically convex $\Rightarrow f(x_k) - f^* = O\left(\frac{m^2}{k}\right)$.

<□ > < □ > < □ > < Ξ > < Ξ > Ξ の Q · 22/31

Orthogonal matrices

A non-trivial example where the assumption holds: **orthogonal matrices** (see Edelman et al. [1998])

$$M := O_n = \{ Y \in \mathbb{R}^{n \times n} : Y^\top Y = YY^\top = I_n \}$$
$$T_Y M = \{ YA : A \in \mathbb{R}^{n \times n}, \ A = -A^\top \in \mathsf{Skew}_n \}$$
$$\langle YA, YB \rangle_Y = \mathsf{Tr}(A^\top B)$$
$$\mathsf{Exp}_Y(YA) = Y \mathsf{Expm}(A).$$

Given $YA \in T_YM$ and $Z = Exp_Y(YC)$, parallel transport of YA from T_YM to T_ZM is

$$\Gamma_Y^Z(YA) = Z \operatorname{Expm}(C/2)^\top A \operatorname{Expm}(C/2).$$

・ロト・四ト・モン・モン・ 正

Orthogonal matrices

Fix
$$X_k = Y_{k,0}$$
. Then $T_{X_k}M = \{X_kA : A \in \text{Skew}_n\}$.

An orthonormal basis for $T_{X_k}M$ is

$$\left\{\frac{1}{\sqrt{2}}X_k(e_ie_l^{\top} - e_le_i^{\top}): 1 \le i < l \le n\right\}.$$

Let m = n(n-1)/2, order the (i, l) indices as $(i_1, l_1), ..., (i_m, l_m)$.

Subspace selection rule for O_n

Pick

$$S_{k,j} = \operatorname{Span}\left(Y_{k,j-1}(e_{i_j}e_{l_j}^{ op} - e_{l_j}e_{i_j}^{ op})
ight) \subset T_{Y_{k,j-1}}M$$

Orthogonal matrices

Let $C_{k,j} \in \text{Skew}_n$ be such that $\text{Exp}_{Y_{k,j-1}}(Y_{k,j-1}C_{k,j}) = X_k$. Parallel transporting the subspaces

$$S_{k,j} = \operatorname{Span}\left(Y_{k,j-1}(e_{i_j}e_{l_j}^{ op} - e_{l_j}e_{l_j}^{ op})
ight) \subset T_{Y_{k,j-1}}M$$

back to $T_{X_k}M$ we have a set

$$\left\{X_k \operatorname{Expm}(C_{k,j}/2)^\top (e_{i_j}e_{l_j}^\top - e_{l_j}e_{l_j}^\top) \operatorname{Expm}(C_{k,j}/2) : j \in [m]\right\}.$$

To prove the assumption: show that when $C_{k,j}$ are small, then the set is "close" to the orthogonal decomposition

$$\left\{X_k(e_{i_j}e_{l_j}^\top - e_{l_j}e_{i_j}^\top) : j \in [m]\right\} \subset T_{X_k}M.$$

Randomized TSD

Pick a subspace decomposition $\{S_k(\xi)\}_{\xi\in\Xi}$ of $T_{x_k}M$ Sample $S_k(\xi)$ at random, $\xi \sim \mathbb{P}$ Set $x_{k+1} = \operatorname{Exp}_{x_k} \left(-t_k P_{S_k(\xi)} \nabla f(x_k)\right)$.

Lemma (Randomized sufficient decrease)

For appropriately chosen step sizes, there exists C > 0 such that we have

$$f(x_k) - \mathbb{E}[f(x_{k+1}) \mid x_k] \geq C \cdot \mathbb{E}\left[\left\| P_{\mathcal{S}_k(\xi)}
abla f(x_k)
ight\|_{x_k}^2 \mid x_k
ight].$$

Convergence

Assumption

There exists $\eta > 0$ such that, for all x, we can construct a subspace decomposition $\{S_x(\xi)\}_{\xi \in \Xi}$ and distribution $\xi \sim \mathbb{P}$ which satisfies

$$\mathbb{E}_{\xi \sim \mathbb{P}}\left[\left\|\boldsymbol{P}_{\mathcal{S}_{\mathsf{x}}(\xi)}\boldsymbol{v}\right\|_{x}^{2}\right] \geq \eta \|\boldsymbol{v}\|_{x}^{2}$$

for any $v \in T_x M$.

Theorem

If the assumption holds, then under suitable regularity conditions on M and f

$$\blacktriangleright \min_{i=0,\ldots,k} \mathbb{E} \left[\|\nabla f(x_i)\|_{x_i} \right] = O\left(\frac{m}{\sqrt{k}}\right).$$

• if f geodesically convex $\Rightarrow \mathbb{E}[f(x_k)] - f^* = O\left(\frac{m^2}{k}\right)$.

A randomized scheme for the Stiefel manifold

$$M := \operatorname{St}(p, n) = \left\{ X \in \mathbb{R}^{n \times p} : X^{\top} X = I_p \right\}$$
$$T_X M = \left\{ XA + \sum_{l \in [p]} b_l e_l^{\top} : \begin{array}{c} A = -A^{\top} \in \operatorname{Skew}_p \\ X^{\top} b_l = 0 \quad \forall l \in [p] \end{array} \right\}.$$

Randomized selection rule

For $T_X M$

$$\begin{split} \text{With probability } 1/(p(p-1)): \quad X(e_ie_l^\top - e_le_i^\top) \\ \text{With probability } 1/(2p): \quad (I_n - XX^\top)z_le_l^\top, \quad z_l \sim N(0,I_n). \end{split}$$

Theorem

With the above randomization scheme,

$$\mathbb{E}_{\xi \sim \mathbb{P}}\left[\left\|P_{\mathcal{S}_{x}(\xi)}v\right\|_{x}^{2}\right] \geq \eta \|v\|_{x}^{2}, \quad \eta = \min\left\{\frac{1}{p(p-1)}, \frac{1}{2p(n-p)}\right\}.$$

Preliminary numerical study

We test deterministic TSD on linear optimization problems in O_n :

$$\min_{Y\in O_n} \operatorname{Tr}(D^{\top}Y).$$

We benchmarked against Riemannian gradient descent.

- ▶ We cycle through the basis $\{Y(e_ie_l^\top e_le_i^\top) : 1 \le i < l \le n\}$.
- This allows efficient computation of the matrix exponential and exact step size selection.
- ▶ Random instances were generated for n = 50, 100, 150, 200.

Results

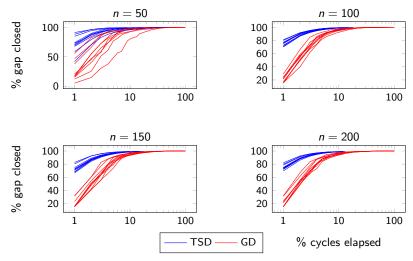

Figure: Results for TSD (blue) vs GD (red). Horizontal axis: cycles elapsed as a percentage of the largest number of cycles for that instance. Vertical axis: gap closed as a percentage of the best objective value found across both algorithms.

Conclusions and future work

Contributions:

- An analogy of coordinate descent to Riemannian manifolds: tangent subspace descent.
- Counterexamples and sufficient conditions for subspace selection rules.
- Convergence guarantees for geodesically convex and nonconvex functions.
- Specific subspace selection rules for Stiefel manifolds.

Future work:

- Schemes for different types of manifolds.
- Proximal setting for composite (smooth + nonsmooth) problems.
- Finite-sum problems.
